

AI Critique

AI was useful for converting a long assignment into a structured Scenario D workflow, mapping 56 checklist items across four screens, and maintaining consistent evidence references. It also highlighted accessibility problems that mouse-only testing can miss, including unnamed controls, validation focus remaining on the submit button, low contrast, and the generic attachment label at `tachment_1`.

Its first analysis was nevertheless too optimistic. Some visually plausible behaviors were initially treated as passes before the required interaction had been executed. A language model can generalize from familiar interface patterns, whereas a tester must require direct evidence for each state. The process was corrected by adding `Pending` and refusing to convert it to `Pass` without a repeatable observation.

AI could not provide genuine evidence for other operating systems, browsers, tablets, or phones. A 320 CSS px viewport test can reveal reflow defects but is not equivalent to a physical mobile environment. Likewise, automated keyboard events, network interception, and Excel download capture were inconclusive, so those checks remain `Pending`. Inventing results or editing screenshots would violate the assignment's evidence rules.

The same integrity rule applies to audit history. The group's original checklist-generation prompts are absent, and reconstructing them would create a false record. Generated imagery was used only as neutral upload input and was kept separate from EMS evidence.

Overall, AI should organize testing, expose assumptions, and automate deterministic checks, not act as the source of truth. Every `Pass`, participant, browser cell, form timestamp, screenshot, and commit must correspond to a real execution. Human review remains necessary for severity, scope, and final submission integrity.
