

AI Critique

The AI was useful for turning a long assignment specification into a structured Scenario D workflow, mapping 56 checklist items across four screens, and maintaining consistent finding fields. It also helped identify accessibility problems that are easy to miss during mouse-only testing, such as an unnamed request-type control, validation focus remaining on the submit button, and the generic attachment label `attachment_1`. However, its first analysis was incomplete. It initially treated several visually plausible behaviours as passes before every required interaction had been executed. This happened because a language model tends to generalise from the visible interface and common design patterns, while a tester must require direct evidence for each state. The process was corrected by introducing a Pending state and refusing to convert it to Pass without a live observation.

The AI also could not independently provide genuine compatibility evidence for macOS, iOS, Android, Safari, Firefox, Edge, Opera, tablets, or phones. Simulating those results or editing screenshots would violate the assignment's evidence rules. Similarly, it could not supply the group's original checklist-generation prompts because they were not present in the workspace. Reconstructing them would create a false audit history. A generated PNG was used only as neutral upload input and was explicitly separated from live EMS screenshots.

The main lesson is that AI should organise testing and challenge assumptions, not act as the source of truth. Every Pass, screenshot, participant, browser cell, form timestamp, and Git commit must correspond to a real execution. Human review remains necessary for severity, scope decisions, and final submission integrity.
